Using the built-in predicates, the sequence of goals, or specifying a goal at the system prompt would be of little value in itself. To write a Prolog program, firstly, the user has to write a program which is written in the Prolog language, load that program, and then specify a sequence of

Execution of a Prolog program is initiated by the user's posting of a single goal, called the query. Logically, the Prolog engine tries to

find a resolution refutation of the negated query. The resolution method used by Prolog is called SLD resolution. If the negated query can be refuted, it follows that the query, with the appropriate variable bindings in place, is a logical consequence of the program.

As is commonly the case in many programming tasks, we often wish to repeatedly perform some operation either over a whole data-structure, or until a certain point is reached. The way we typically do this in Prolog is by recursion.
