Vegetation type and structure can influence microbial activity through direct and indirect mechanisms such as: (1) Modification of microclimate; (2) Alterations in the quantity and quality of litter; (3) The supply of root exudates, and/or; (4) The above-below ground allocation patterns of organic matter (De Deyn et al., 2008; Wardle et al., 2012; Jassey et al., 2013).

Parenchyma cells are the most common plant cells (Figure 8). They are found in the stem, the root, the inside of the leaf, and the pulp of the fruit. Parenchyma cells are responsible for metabolic functions, such as photosynthesis, and they help repair and heal wounds. Some parenchyma cells also store starch.

The primary function of the cell wall is to protect and provide structural support to the cell. The plant cell wall is also involved in protecting the cell against mechanical stress and to provide form and structure to the cell. It also filters the molecules passing in and out of the cell. The formation of the cell wall is guided by microtubules.
